# 1 Goal :

- The goal is to implement TAS, CAS and Bounded Waiting with CAS mutual exclusion (ME) algorithms and comparing the average time required by a thread to enter critical section and comparing the maximum time required by a thread to enter critical section by varying the number of threads.

# 2 Input :

- The inputs are given by text file **inp-params.txt** and are:
  - Number of threads used in the program ( $N$ )
  - Number of times each thread enters CS ( $K$ )
  - $\lambda_1$  is the mean of exponential distributed delay values for  $t_1$  in milliseconds.
  - $\lambda_2$  is the mean of exponential distributed delay values for  $t_2$  in milliseconds.

# 3 Output :

- We have three output files for each ME :
  1. TAS ME output (*tas\_output.txt*)
  2. CAS ME output (*cas\_output.txt*)
  3. Bounded CAS ME output (*cas\_bounded\_output.txt*)

# 4 Analyzing Program Output Files:

## 1) TAS ME Output :

- We can observe that there isn't any significant change between the times of Entered, Exited and Entered to entering of a new process to CS as the sleep time begins in milliseconds.
- As the value of number of threads reaches the max value of 50 we get an atmost time difference of 2 min, for small values of number threads there isn't any significant change in time between first and last write to the file.
- The output demonstrates the mutual exclusion of TAS, as when we see Requested, Entered, Exited these all occur for a write in sequential order which means that the property of mutual exclusion is followed, as there isn't any other process interrupting our executing process.
- The printing was done not in order to demonstrate the validity of mutual exclusion.

## 2) CAS ME Output :

- The time difference between times of Entered, Exited and Entered to entering of a new process to CS are very much near because of sleep time begins in milliseconds.
- Mutual exclusion can be understood by seeing the pattern of output, which are in regular pattern of Requested, Entered, Exited for a single thread.
- The printing was done not in order to demonstrate the validity of mutual exclusion.

### 3) Bounded waiting CAS ME Output :

- The time difference between times of Entered, Exited and Exited to entering of a new process to CS are very much near because of sleep time being in milli seconds.
- Mutual exclusion can be understood by seeing the pattern of output, which are in regular pattern of Requested, Entered, Exited for a single thread.
- The printing was done not in order to demonstrate the validity of mutual exclusion.

## 5 Analyzing Graphs :

- We analyze the program in two modes:
  1. Average time taken to enter the CS by each thread with varying the number of threads.
  2. The worst case time taken by a process to enter the CS with varying the number of threads.

### 5.1 Graph 1 :

- The value of  $K$  used by the program is fixed and is equal to 10.
- Now we see the variation of average time of entering into CS ( $T$ ) by varying the number of threads ( $N$ ).

#### 5.1.1 Graph :

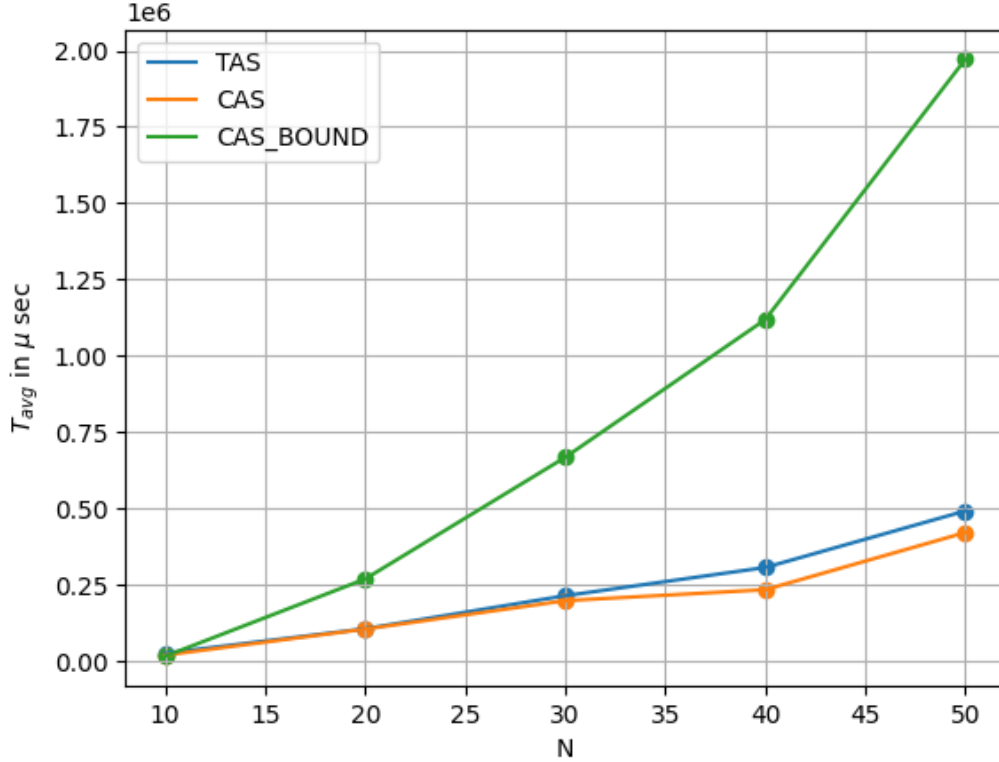

Figure 1:  $T_{avg}$  vs  $N$

### 5.1.2 Observations :

- From the graph we can observe that using *TAS* or *CAS* we get nearly the same entering average time into CS.
- Average entering time is highest in case of *Bounded – CAS*.

## 5.2 Graph 2 :

- The value of  $K$  used by the program is fixed and is equal to 10.
- Now we see the variation of max time of entering into CS ( $T$ ) by varying the number of threads ( $N$ ).

### 5.2.1 Graph :

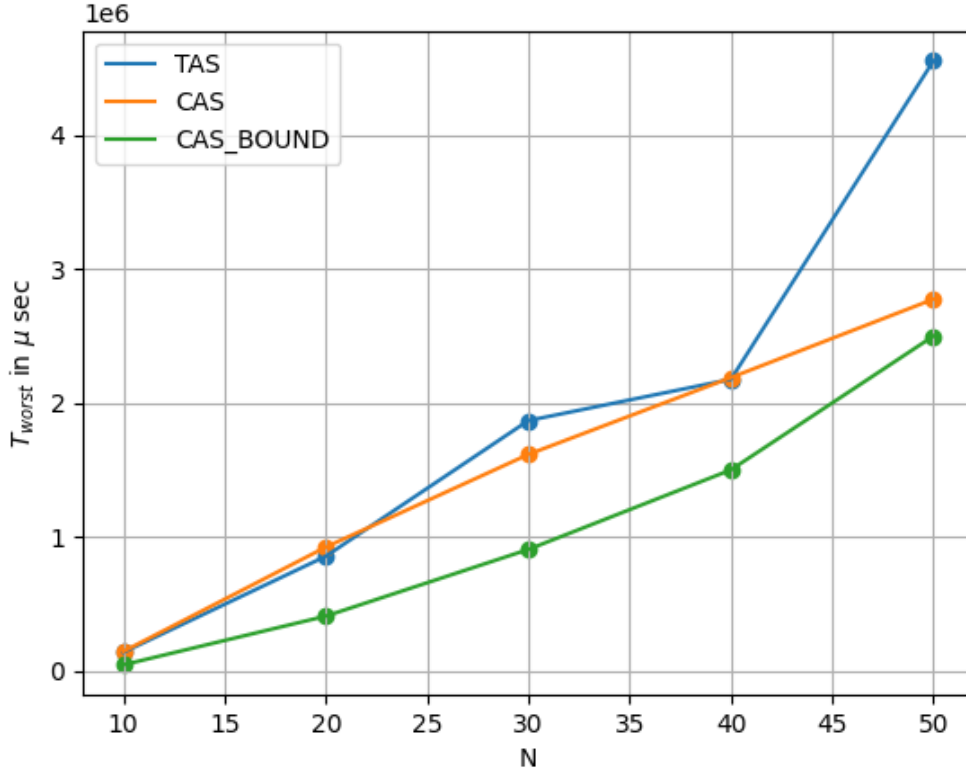

Figure 2:  $T_{\text{max}}$  vs  $N$

### 5.2.2 Observations :

- From the graph we can observe that using *TAS* or *CAS* we get nearly the same maximum entering time into CS for small values of  $N$ , but as value of  $N$  increases for *TAS* maximum entering time increases rapidly.
- Maximum entering time is lowest in case of *Bounded – CAS*.

## 6 Final Conclusion:

- Maximum entering time is lowest in case of *Bounded – CAS*, and Average entering time is highest in case of *Bounded – CAS*.
